“Assessment of exercise capacity in cardiovascular disease. Insights from a CPET approach”

Damiano Magrì, M.D., Ph.D.

DIPARTIMENTO DI MEDICINA CLINICA E MOLECOLARE

The exercise capacity is the essence of human beings. Similarly to what happens in many other disease settings, also in the cardiovascular diseases' one, a progressively impairment of functional capacity characterizes both their clinical course and outcome. In such a context, the cardiopulmonary exercise test (CPET) represents the best non-invasive approach to obtain a comprehensive functional as well as prognostic assessment. Furthermore, CPET-derived data might help the physician in the identification of the most likely mechanisms underlying the functional impairment, in monitoring therapeutic responses and, in specific cases, in selecting the most appropriate therapeutic option.
